hourly peak in the work of Engle *et al* (

of differing frequencies used to approximate a given function

As most of the regressors in ( ) are dependent on the time being forecasted predictions based on this model are simple to produce. Because the short run model includes indicator variables for a base year for predictions is necessary. The year variable must be within the sample period but the other calendar variables should reflect the actual year of the forecast to accurately represent when holidays and weekends occur. Once a given time frame is decided, pertinent

Because the diurnal load data used to estimate the short term diurnal model represents only a small subset of all commercial and industrial customers in each of the four states the diurnal load profiles generated by model ( ) are scaled to represent aggregate statewide consumption. This is done by comparing the total quantity demand in ( ) in the short run data sets to aggregate statewide consumption reported by the EIA. If we let  $A_y$  denote aggregate annual statewide consumption and  $Q_t$  the hourly consumption of the customer subset in the diurnal data the scaling factor for the year is given by

$$S_y = \frac{A_y}{\sum_t Q_t} \quad (8)$$

For instance the hourly quantity demand by the subset of commercial and industrial customers in Ohio in ( ) is approximately 15% of the total statewide consumption thus the outputs of model ( ) are scaled by a factor of 6.7 to forecast statewide commercial and industrial consumption. This scaling factor is applied to all of the hourly loads generated by the short term model and is included in Figure 4 and all subsequent figures.

Figure 1 Actual and predicted values of gross state product in Virginia for the years 1990-2008.  $R^2 = 0.98$

Table 1 Regression estimates for short term models in equations (1) and (2) for Michigan. Regression  $R^2$ 's are 0.95 and 0.97 respectively. Model (1) has a Durbin-Watson statistic of 1.98

Variable	Equation (1)		Equation (2)	
	Coefficient	t value	Coefficient	t value
Constant	-1.2	-0.1	-1.5	-0.1
HD	0.8	1.2	0.8	1.2
CD	0.5	0.7	0.5	0.7
HD	-	-	-	-
CD	-	-	-	-
Day Hot	0.7	1.5	0.7	1.5

Table 1: Regression estimates for short term models in equations (1) and (2) for Ohio. Regression  $R^2$ 's are 0.88 and 0.92 respectively. Model (1) has a Durbin-Watson statistic of 1.88.

Table 1. Regression estimates for short term models in equations (1) and (2) for Texas. Regression  $R^2$ 's are 0.15 and 0.17 respectively. Model (1) has a Durbin  $D$  statistic of 0.15.
